ABSTRACT OF THE DISCLOSURE

A node information management system including a plurality of
nodes (1i) connected through a network and an information collecting
apparatus (10) connected to the nodes so as to collect predetermined
information regarding each node.   Each node has: a memory unit (122) which
stores the predetermined information formed by the node itself every
formation of the information; a transmitting unit (120) which supplies the
predetermined information stored in the node information memory unit of the
node itself to another node; and a backup memory unit (123) which stores the
predetermined information supplied from the node information transmitting
unit of such another node.   The node information is hardly lost and a load of a
collecting process of the node information collecting apparatus is reduced.
